

An Uneven Crisis: Firearm Suicide in the United States

Firearm Suicide in the United States

Firearm suicide is rising across the United States, but the burden is not shared equally across regions.

Firearm Suicide Remains the Dominant Form of Gun Deaths
Suicide consistently exceeds homicide from 1999–2015

National Trends

Firearm suicide consistently remains the leading form of gun-related mortality in the United States and continues to rise over time, signaling a persistent and growing public health crisis.

Firearm Suicide Rates Were Already Elevated in Parts of the U.S. (2000)

Geographic Concentration of Firearm Suicide Deepend Over Time

Geographic Trends

Firearm suicide rates vary widely across the United States and have increased over time. From 2000 to 2015, most states darkened, indicating rising rates nationwide.

However, the increase is not uniform. The South and Mountain West consistently show the highest rates, while the Northeast remains relatively lower. Overall, the maps reveal both a national rise and persistent regional inequality in firearm suicide.

Firearm Suicide Rates Reveal Persistent Regional Divides Across the United States (1999–2015)

Persistent Regional Inequality

Firearm suicide rates increased across all U.S. regions from 1999 to 2015, but stark geographic disparities persist. The South and West consistently experience the highest rates, while the Northeast remains lowest. The Midwest shows the steepest increase, signaling rapidly growing risk.

Overall, the burden is rising nationwide, but regional inequality remains entrenched rather than converging.

Data: CDC WONDER. Firearm suicide rates are calculated per 100,000 population using aggregated death counts and population estimates
